

Adiabatic master equation with spin-fluctuators

Huo Chen

November 19, 2020

0.1 Model setup

In this example notebook, we solve the master equation of the following form

$$\dot{\rho} = -i[-Z + \delta(s)Z, \rho] + \mathcal{L}(\rho)$$

via trajectory method. In above expression, \mathcal{L} is the Davies generator for the adiabatic master equation. $\delta(s)$ is a classical stochastic process generated by summing multiple telegraph processes together:

$$\delta(t) = \sum_{i=1}^N T_i(t) ,$$

where $T_i(t)$ switches randomly between $\pm b_i$ with rate γ_i . In the following code block, we show how to construct such a process:

```
using OrdinaryDiffEq, OpenQuantumTools
using Plots, StatsBase

H = DenseHamiltonian([(s)->1.0], [-σz], unit=:ħ)
u0 = PauliVec[1][1]

coupling = ConstantCouplings(["Z"], unit=:ħ)
# number of fluctuators
num = 10
# The values of b created here are in angular frequencies unit
bvec = 0.01 * ones(num)
# γ_i
γvec = log_uniform(0.01, 1, num)
# create the fluctuator coupling interaction
fluctuator_ensemble = EnsembleFluctuator(bvec, γvec);
interaction_fluctuator = Interaction(coupling, fluctuator_ensemble)
# create the Ohmic coupling interaction
ohmic_bath = Ohmic(1e-4, 4, 16)
interaction_ohmic = Interaction(coupling, ohmic_bath)
# merge those two bath object into `InteractionSet`
interactions = InteractionSet(interaction_fluctuator, interaction_ohmic)
annealing = Annealing(H, u0, interactions=interactions)

Annealing with hType QTBBase.DenseHamiltonian{Complex{Float64}} and uType Array{Complex{Float64},1}
u0 with size: (2,)
```

0.2 Dynamics

Then we solve the dynamics and calculate $\langle X \rangle$ during the evolution:

```
tf = 100
prob = build_ensembles(annealing, tf, :ame,  $\omega_{\text{hint}} = \text{range}(-2, 2, \text{length}=100)$ )
t_list = range(0,tf,length=200)
sol = solve(prob, Tsit5(), EnsembleSerial(), trajectories=1000, reltol=1e-6,
saveat=t_list)

dataset = []
st(s, so) = normalize(so(s, continuity=:left))
for s in t_list
    push!(dataset, [real(st(s, so)' *  $\sigma_x$  * st(s, so)) for so in sol])
end

pop_mean = []
pop_rmse = []
for data in dataset
    p_mean = sum(data)/1000
    p_rmse = sqrt(sum((x)->(x-p_mean)^2, data))/1000
    push!(pop_mean, p_mean)
    push!(pop_rmse, 2*p_rmse)
end
```

We also solve the dynamics with pure Ohmic bath, i.e. the adiabatic master equation:

```
a_list = range(0,tf,length=400)
annealing_ame = Annealing(H, u0, coupling=coupling, bath=ohmic_bath)
sol_ame = solve_ame(annealing_ame, tf, alg=Tsit5(),  $\omega_{\text{hint}} = \text{range}(-2, 2, \text{length}=100)$ ,
    reltol=1e-6, saveat=a_list)
ame_x = [real(tr(u* $\sigma_x$ )) for u in sol_ame.u]
```

We compare $\langle X \rangle$ obtained using the above two models:

```
plot(a_list, ame_x, label="Ohmic", linewidth=2)
plot!(t_list, pop_mean, ribbon=pop_rmse, label="Hyrbrid", linewidth=2)
xlabel!("s (ns)")
ylabel!("<X>")
```
